Normal depth is the depth of uniform flow in an prismatic open channel. Since the flow is uniform, the depth and discharge are related through Manning's equation with $S_f = S_o$. 3.15 Given Q , n , $A(y)$, $R_h(y)$ and S_o : solve for y_n Waves (Small Disturbances) in a Moving Stream y_c V Wave (disturbance) can move upstream if 3.16 Froude

The Manning formula can be used to calculate the flow of water in open non-full channels and pipes without the need for a flume, weir, or other structure. While not as accurate as flows calculated with those structures, the Manning formula is accurate enough for some applications.

Open-channel flow, a branch of hydraulics and fluid mechanics, is a type of

liquid flow within a conduit with a free surface, known as a channel. The other type of flow within a conduit is pipe flow. These two types of flow are similar in many ways but differ in one important respect: the free surface. Open-channel flow has a free surface, whereas pipe flow does not.

In a uniform channel with steady flow, it is equal to the slope of the total head line (ft./ft.). So= Slope of the flow line of a conduit (bed slope). With a steady uniform flow, the water surface, the total head line, and the flow line are all parallel and $80=81$ (ft./ft.).

empirical formula estimating the average velocity of a liquid flowing in a conduit that does not completely enclose the liquid, i.e., open channel flow. However, this equation is also used for calculation of flow variables in case of flow in partially full conduits, as they also possess a free surface like that of open channel flow.
